Abstract

To explore the impact of sulfur (S) fertilization on copper (Cu) metabolism in grazing Tibetan sheep, fertilizing and grazing experiments were conducted in the Southwest Grand Grassland, China. The tested pasture was randomly divided into four parts by the fencing device (2 hm²/part). The pasture received ammonium sulfate [$(NH_4)_2SO_4$] treatment in summer in 2020 (0, 300, 400, and 500 kg/hm² for part I, part II, part III, and part IV, respectively). 24 Tibetan sheep (one year old) were randomly divided into four groups, and assigned to the selected pastures (part I, part II, part III, and part IV for group I, group II, group III, and group IV, respectively). The grazing experiments lasted for 90 days. The results showed that the contents of nitrogen (N) and S in fertilized forage were markedly higher than those in unfertilized grass ($P<0.01$), but there w**as** no significant difference among fertilized forages. The contents of Cu in blood and liver in the Tibetan sheep from fertilized pasture were extremely lower than those in animals from unfertilized pasture ($P<0.01$). The contents of Hb and PCV in the tested sheep from fertilized pasture were extremely higher than those in sheep from unfertilized pasture. The activities of serum SOD, GSH-Px, T-AOC, Cp, and CAT in sheep from fertilized pasture were extremely lower than those in sheep from no fertilized pasture ($P<0.01$), but there were no obvious differences among the Tibetan sheep from fertilized pasture ($P>0.05$). The contents of MDA in the Tibetan sheep from fertilized pasture were significantly higher than those in animals from no fertilized pasture ($P<0.01$). There was no obvious difference among the Tibetan sheep from fertilized pasture (P>0.05). Therefore, $(NH_4)_2SO_4$ fertilization not only greatly influenced the contents of S and N

*e-mail: xyshen@swust.edu.cn

in forage, but also extremely decreased Cu contents of animal tissues in the Tibetan sheep from fertilized ranges.

Keywords: the Southwest Grand Grassland, pastureland management, tibetan sheep, copper metabolism, sulphur fertilizer

Introduction

The Qinghai-Tibet Plateau is an alpine meadow ecosystem of the highest altitude in the world, and is also the largest pasture land in Southwest China [1]. The Southwest Grand Grassland is located in the Southeast of the Qinghai-Tibet Plateau, and is also the highest primary productivity in Asia. Tibetan sheep, Hequ horse, and Choko yak are born and bred there [2, 3].

Tibetan sheep are vital to the production system of the Southwest Grand Grassland, China. Over the last 10 years, the local government was trying to improve the nomadic lifestyle of local herdsmen. More and more natural pastures were fenced in the Southwest Grand Grassland. The feeding areas of the Tibetan sheep had been rigorously restricted in fenced pasture, and nomadic behavior had been seriously interrupted. As a result, sulfur (S) deprivation had sharply risen in forage in the Southwest Grand Grassland [4, 5]. S as a nutrient is very important in plants and animals [6, 7]. In recent years, to improve productivity, the local herdsmen are trying to increase S content in forage. Ammonium sulfate $[(NH_4)_2SO_4]$ fertilization was conducted during the summer grazing season in the Southwest Grand Grassland. Molybdenum (Mo) content in forage is a commonly recognized contributor to copper (Cu) deprivation in animals, but adequate dietary S nutrient is required. Mo combines with S element to form thiomolybdate complex, and binds with Cu element to form insoluble complex, rendering Cu nutrient unavailable for absorption [8]. Therefore, the effect of increasing S concentration in forage on mineral status of grazing Tibetan sheep is an important issue. Shen has reported that the effect of $(NH_4)_2SO_4$ treatment on S contents of plants in natural pasture in the Shouqu Prairie in Southwest China. In this study, $(NH_4)_2SO_4$ fertilization resulted in high S contents in plant (0.71%) compared to fertilized plant with ammonium nitrate (NH_4NO_3) (0.18%) [9]. Nevertheless, the effects of different levels of $(NH_4)_2SO_4$ fertilization on Cu metabolism have not been reported in grazing Tibetan sheep.

The objective of this research was to determine the influences of different levels of $(NH_4)_2SO_4$ fertilization on Cu metabolism of grazing Tibetan sheep in the Southwest Grand Grassland.

Materials and Methods

Experiment Design

$(NH_4)_2SO_4$ was purchased from Xinan Chemical Industry Group Co., Ltd, with purity of no less than 99%. The tested pasture is located in the Southwest Grand Grassland in Sichuan Province, China. The mineral elements in soil were determined at the start and end of the research. The tested pasture was randomly divided into four parts by the fencing device (2 hm^2/part). The pasture received $(NH_4)_2SO_4$ treatment in summer in 2020 (0, 300, 400, and 500 kg/hm^2 for part I, part II, part III, and part IV, respectively). A total of 24 Tibetan sheep were randomly divided into four groups, and assigned to the selected pastures (part I, part II, part III, and part IV for group I, group II, group III, and group IV, respectively). The grazing experiment lasted for 90 days.

Sample Collection

The samples of soil and plant were collected at the start and end of the experiment. The samples of whole blood were collected from the jugular vein at the end of the experiment. The samples of serum were collected in vacuum tubes of 1% heparin sodium, centrifuged at 3 000×g for 15 min, then stored at 4ºC. The samples of liver were collected by a trained technician using techniques previously described.

Sample Analysis

The samples of soil and forage were analyzed for mineral contents as described for Yuan (2012) [8]. The samples of blood and liver were handled and analyzed for mineral contents of Cu, zinc (Zn), manganese (Mn), iron (Fe), and Mo as described for Huo et al. (2019) [10]. The contents of nitrogen (N) and S in soil and forage were analyzed as described for Shen (2009) [9].

The blood physiological parameters including hemoglobin (Hb), erythrocyte count (RBC), packed cell volume (PCV), and white blood cell count (WBC) were analyzed as described for Yuan et al. (2013) [11]. The blood biochemical parameters including total antioxidant capacity (T-AOC), superoxide dismutase (SOD), glutathione peroxide (GSH-Px), catalase (CAT), malondialdehyde (MDA), and ceruloplasmin (Cp) were analyzed as described for Shen (2011) [12].

Data Analyses

The tested data was analyzed by the statistical package (SPSS, version 21.0, Inc., Chicago, Illinois, USA), and presented in the form of mean±standard deviation.

Results

Influences of S Fertilization on Mineral Content in Forage S

As in Table 1, compared to unfertilized pasture (control group), the values of S and N in forage were considerably higher in fertilized pasture ($P<0.01$), and the values of Cu in forage were considerably lower in fertilized pasture ($P<0.01$), nevertheless there was no considerable difference among part II, part III, and part IV ($P>0.05$).

Influences of S Fertilization on Mineral Content in Animal Tissues

As in Table 2 and Table 3, the Cu values in blood and liver in group I (control group) were considerably higher than those in group II, group III, and group IV ($P<0.01$), nevertheless there was no considerable difference among group II, group III, and group IV ($P>0.05$). The S values in blood and liver in group I (control group) were considerably lower than those in group II, group III, and group IV ($P<0.01$), nevertheless there was no considerable difference among group II, group III, and group IV ($P>0.05$). The Fe values in blood in group I (control group) were extremely higher than those in group II, group III, and group IV ($P<0.01$). There were no considerable difference among Fe contents in liver in group I, group II, group III, and group IV ($P>0.05$).

Influences of S Fertilization on Physiological Parameters in Grazing Animals

As in Table 4, compared to group I (control group), the values of Hb and PCV were considerably decreased in group II, group III, and group IV ($P<0.01$), nevertheless there was no considerable difference among group II, group III, and group IV ($P>0.05$). Anemia has occurred in group II, group III, and group IV.

Influences of S Fertilization on Antioxidant Parameters in Grazing Animals

As in Table 5, compared to group I (control group), the levels of T-AOC, SOD, GSH-Px, CAT,

and Cp in serum were considerably decreased in group II, group III, and group IV ($P<0.01$), and the levels of MDA were considerably increased in group II, group III, and group IV ($P<0.01$), nevertheless there was no considerable difference among group II, group III, and group IV ($P>0.05$).

Discussion

Influences of S Fertilization on Mineral Contents in Forages

N and S are important nutrients in plants. More and more studies have shown that fertilized forages with $(NH_4)_2SO_4$ can considerably increase the contents of N and S in plants. Shen has also reported a 3-year study on investigating the effect of $(NH_4)_2SO_4$ treatment on S contents of plants in the Shouqu Prairie in Southwest China) [9]. Their results showed that the contents of N and S in forage were considerably increased in fertilized pasture. Nevertheless, to date, no researcher has investigated the influences of different levels of $(NH_4)_2SO_4$ fertilization on Cu metabolism in grazing animals.

Influences of S Fertilization on Mineral Contents in Animal Tissues

The antagonistic effect of S nutrient on Cu metabolism in animals has been very well recognized. S element combines with Mo element to form a thiomolybdate complex in rumen. Thiomolybdates bind with Cu element to form an insoluble complex, rendering Cu nutrient unavailable for absorption. Therefore, the Cu values in blood and liver in group I (control

group) were considerably higher than those in group II, group III, and group IV. Decrease in circulating Cu level in blood is associated with Cu content in liver of approximately 40 mg/kg and lower [13, 14]. Once these contents are achieved, sheep are considered Cu deprivation. Cu content in liver below 75 mg/kg is considered deprivation for the Tibetan sheep [15, 16]. Therefore, the Tibetan sheep in current studies had been considered Cu deprivation when they initially entered the experiment, because initial Cu contents in liver in the tested sheep were 73.26±6.17 mg/kg.

Influences of S Fertilization on Physiological Parameters in Grazing Animals

Most of Cu element in blood is showed as ceruloplasmin (Cp), which plays a key role in greatly increasing the rate of Fe saturation of transferrin, so in the absorption and transport of Fe, and in the utilization of Fe by the bone marrow in animals [17, 18]. The lack of Cu nutrient often leads to extreme decrease of Cp content in blood [19-21]. Therefore, the low content of Cu in forage not only considerably reduces the level of Cp but also causes sheep anemia. In our studies, the values of Hb and PCV were considerably lower than those in group II, group III, and group IV.

Influences of S Fertilization on Antioxidant Parameters in Grazing Animals

SOD per mole contains 2 eq (chemical equivalent) of Cu. Cu element may be reversibly removed, and it is required for activity [22, 23]. Cu deficiency often leads to low Cp content in blood, and decreases absorption of Fe [24, 25]. Therefore, the levels of T-AOC, CAT, and SOD in the Tibetan sheep from fertilized pastures were extremely decreased, and the contents of MDA were considerably increased. Antioxidant system is the defense system of organisms for scavenging free radicals, including mainly vitamins, cysteine, glutathione, Cu, Mn, Zn, Fe, SOD, GSH-Px, CAT, etc [26, 27]. SOD, as a key metal enzyme, is very widely existing in aerobic organisms. It plays a very important role in the oxidation resistance of organisms, and can very rapidly catalyze the superoxide anion (O^{2-}) to produce disproportionation reaction, and protect organism cells from damage from free radicals in metabolism [28-30]. CAT can decompose H_2O_2 into molecular oxygen and water very rapidly and clear H_2O_2 in organism, so as to protect organism cells from H_2O_2 [31-33]. T-AOC is an important parameter for evaluating antioxidant capacity in organisms. It can very rapidly reflect the compensatory capacity to external stimuli and the metabolism capacity of free radicals in organisms [34-36]. The significant decrease of T-AOC level will considerably increase the abundance of lipid peroxides and free radicals of organisms. MDA is a lipid peroxide of organism, which can reflect very rapidly the degree of lipid peroxidation in organisms [37-39].

Conclusion

Based on the results, the fertilized pasture not only increased the contents of S and N in forage, but also severely disrupted the blood parameters and considerably decreased Cu contents in blood and liver.

Acknowledgements

Compliance with Ethical Standards

Tested Tibetan sheep were cared for as outlined in the Guide for the Care and Use of Tested Animals in Research and Teaching Consortium. Sample collections from the Tibetan sheep were approved by Southwest University of Science and Technology, Institutional Animal Care and Use Committee (Project B-0197). The studies were approved by the relevant ranchers, with the written consent of all participants.
